

Muscle signals can pilot a robot

By Brandon Truong and Zetao Wu

June 1, 2020

Who made it?

- MIT's Computer Science and Artificial Intelligence Laboratory (CSAIL) came up with it
 - called "Conduct-A-Bot" which uses human muscle signals from wearable sensors to pilot a robot's movement.
- Finished experiment during March 2020
 - Purpose to largely reduce the barrier to casual users interacting with robots
 - Experiment involved controlling a drone with muscle sensors

● How does it work?

- Uses wearable surface electromyography (EMG) sensors and an inertial measurement unit (IMU) to detect muscle signals
 - Includes detecting arm stiffening, fist clenching, rotation of arm and left/right/up/down motion.
- Online clustering algorithm helps interpret these signals
 - Allows processing of gesture in real time without calibration and user data
 - Neural network of previous data supplements algorithm
 - Predicts wrist flexion and rotation from forearm muscle signals

Gesture Interpretation

Pros:

- Increased robustness by separating movement into easily interpretable gestures, thus improving accuracy.
- Increased deployability through reducing need of external equipment
- Requires only 2-3 wearable sensors rather than cameras and motion capture
- Less susceptible to environmental noise

Cons:

- Predefined gesture library sacrifices full control of movement for precision
- Wearing muscle sensors can be irritating during extended use

Intuitive and Force Recognition

Advantages of Using Muscle Control

- Easier to learn
- Easier to control for beginners
- You can feel how much force you are putting into an action

Online clustering algorithm

- Builds on Gaussian Mixture Models (GMM) to create a good model of gestures, movement, relaxation
- Streaming data online allows for no predefined GMM, dynamically creates a new GMM to fit the user from scratch

Software Overview

Algorithm 1: Online Clustering of Streaming Data

Input: n -dimensional signal sample $sample^{1 \times n}$
Params: k , history length H , T_{refit} , $T_{initialize}$, $zscore_bounds$
Output: cluster prediction $K_{predicted}$

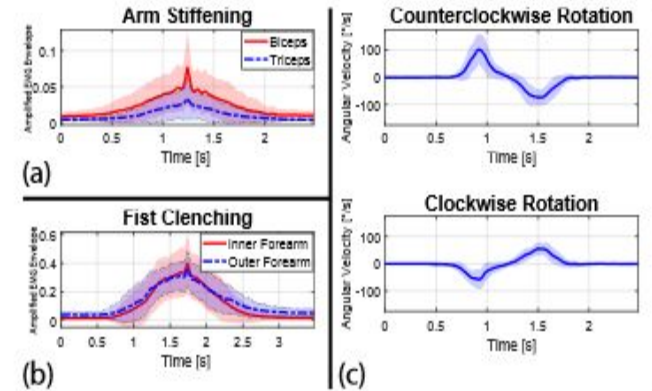

```
1: Initialize  $k + 1$  rolling buffers:  $histories^{(k+1) \times H \times n}$ 
2: while current time  $< T_{initialize}$  do
3:    $histories[k + 1] \leftarrow sample$  // store as unknown cluster
4: if  $T_{refit}$  seconds since last GMM fit then
5:    $allSamples^{H(k+1) \times n} = \text{concatenate all } (k + 1) \text{ histories}$ 
6:    $gmm = \text{FitModel}(allSamples, k)$ 
7:    $K_{all}^{H(k+1) \times 1} = \text{PredictCluster}(gmm, allSamples[i]) \forall i$ 
8:    $histories[c] = allSamples[K_{all} == c] \forall c = 1 \dots k$ 
9:    $histories[k + 1] = []$ 
10:  $K_{predicted}^{1 \times 1} = \text{PredictCluster}(gmm, sample)$ 
11:  $histories[K_{predicted}] \leftarrow sample$ 
    Function  $\text{PredictCluster}(gmm, sample)$ :
12:    $[posteriors^{1 \times k}, zscores^{1 \times k}] = \text{EvalGMM}(gmm, sample)$ 
13:    $K_{predicted} = \text{cluster with } \max(posteriors)$ 
14:   if any of  $zscores$  violate  $zscore\_bounds$  for  $K_{predicted}$  then
      $K_{predicted} = k + 1$  // mark as unknown cluster
```

- Buffer to store info before system is initialized
- Fit all data and predicts a good model based on it
 - Tests for z-score, statistic value for checking deviation

Hardware Overview

- Uses two EMG electrodes attached to upper arm
- Attached to triceps brachii and biceps brachii to detect muscle signals at upper arm
- 8 dry EMG electrodes on upper forearm samples muscle activity below the elbow
- IMU containing accelerometer and gyroscope detects rotation and acceleration of forearm.
- Upper arm sends data to data acquisition (DAQ) device and through USB while forearm sends data through Bluetooth to Simulink R2018b

Results

- Classifiers identified 97.6% of 1200 cued open-loop gestures
 - Repeated patterns and gestures
- 81.6% of 1535 unstructured gestures was responded to by the robot (closed-loop)
 - Real life application of piloting a drone through hoops
 - Errors may have resulted from multiple gestures in a given time or change in handling (accelerating/rotating quicker than before)

(b)

	Total Count	Stiffen	Fist	CW	CCW	Left	Right	Up	Down	None
Stiffen	143	84.6% (14.0%)						1.4% (14.0%)		
Fist	327		82.6% (0.9%)			15.0% (1.5%)				
CW	212	8.5% (76.4%)		1.4% (0.5%)						13.2%
CCW	342	0.9% (0.3%)		1.5% (98.8%)		0.3% (0.3%)				1.5%
Left	174		2.9% (2.3%)	1.1% (1.1%)		67.2% (1.7%)				24.7%
Right	121	0.8% (0.8%)		1.7% (2.5%)			88.4% (0.8%)			5.0%
Up	131		3.1% (2.3%)	8.4% (8.4%)				78.3% (9.9%)		
Down	85		1.2% (11.8%)	9.4% (9.4%)				2.4% (57.8%)	17.6% (17.6%)	
None		1	5	3	2	36	11		2	
		Stiffen	Fist	CW	CCW	Left	Right	Up	Down	None

● Its Significance

- Reduces need for user to calibrate
- Increases range of possible motions by using muscle signals
 - Can tell how much force and torque to put into action

Possible Applications

- Remote handling
 - Can benefit those in hazardous jobs/ those that handle hazardous chemicals by improving safety through remote robotic movement without sacrificing accuracy
 - Ex. chemical waste management, industrial machinery operation, decontamination of rooms, etc.
